Brandon Glajchen

Linux

This code used a loop until the exit command was given to keep taking in inputs. It would then parse the line apart using the whitespace as delimiters, and store the tokens in the buffer. Going over each of the buffer items individually, it would pass them into a function to properly deal with them. A few commands were built in to the code, like 'cd', 'help', and 'exit'. Otherwise, the program would pass the commands into the system to be able to handle them normally.
